Effect of GA₃ and Potassium Nitrate in Different Dates on Fruit Set, Yield and Splitting of Washington Navel Orange

*Abd El-Rahman, G.F.; Hoda, M.Mohamed and Ensherah, A.H.Tayh

Citrus Department, Hort. Res. Instit., Agric. Res. Center, Giza, Egypt *gamalelashmanty@yahoo.com

Abstract: Two concentrations of GA₃ were used alone or with 0.5% urea i.e. (50 and 100 ppm) and three levels of potassium nitrate (KNO₃₎ 2 · 4 and 6% were tested as foliar sprays at different times i.e. first time application at full bloom stage, the second time application was at fruit diameter from 1.5-2.0 cm and (first and second time of application) for investigation their effects on fruit set, yield, fruit quality and splitting of 40-years-old Washington navel orange(Citrus Sinensis), trees budded on Sour Orange (Citrus aurantium, L.Obseck) rootstock during 2008 and 2009 seasons. Data indicated that, all treatments increased fruit set, yield and fruit quality and decreased fruit splitting as compared with control treatment. Data also revealed that, foliar sprays of trees by (GA₃ at 50 ppm) with or without 0.5% urea were superior for inducing the highest increase of fruit set and yield, in addition KNO₃ at 4% comparing with 2% and 6%. Also, KNO₃ treatments increased fruit size, peel thickness and juice acidity especially with high concentrations; on the other hand, the use of GA₃ at 50 or 100 ppm alone or with 0.5% urea increased fruit T.S.S and reduced nitrite and nitrate contents in fruit juice as compared with KNO₃ treatments. Moreover, it is noticed that trees sprayed at first application or first and second time of application gave the best results, while second application was the best for reducing fruit splitting. It could be recommended the best treatment for increasing yield and gave high fruit quality is GA₃ at 50 ppm with or without 0.5% urea at full bloom stage especially in respect with reducing nitrite and nitrate in fruit juice, and use KNO₃ 4% at the second time of application to reduce fruit splitting.

[Abd El-Rahman, G.F.; Hoda, M.Mohamed and Ensherah, A.H.Tayh Effect of GA₃ and Potassium Nitrate in Different Dates on Fruit Set, Yield and Splitting of Washington Navel Orange] Nature and Science 2011; 9(12): 196-204]. (ISSN: 1545-0740). http://www.sciencepub.net 27

Key word: GA₃ Navel Orange, KNO₃ Fruit Set, Yield

1. Introduction

Navel orange is a popular fresh fruit due to its seedless, large size, characteristic flavor and aroma (Wardowski, et al., 1985). Also, navels orange are in important source of early season income for citrus growers in some commercial citrus areas of the world. Yields are erratic and usually low in many areas due to lack functional pollen, rarely produce viable ovules and in addition, are weakly parthenocarpic (Krezdorn, 1965). Flower and fruit drop of navel orange occurred in three phases and amount to a total 91%, giving a fruit set of 9% (Villafane, et al., 1989). Gibberellic acid (GA₃) and potassium nitrate have a board range of uses in citriculture; Gibberellins have been used in citrus production with several objectives including bloom reduction, increased fruit setting, improvement of fruit quality and improved maturation control (Agustí and Almela, 1991). The application of gibberellic acid soon after flowering at doses between 10 and 15 ppm can result in delayed abscission and increased fruit set, mainly in Clementine tangerines (Fornes et al., 1992; El-Otmani, 1992). However, the increase in fixing and productivity does not happen frequently and depends on factors including variety, plant status and time of application (Davies, 1987; Talón et al.,

1997). Also, GA₃ increased fruit set in navels orange (Smith, 1993; Babu and Lavania, 1985), in tangerine hybrids (Brosh and Monselise, 1977) and increased the yield either as number or weight of fruits per tree of Washington navel orange (Ibrahim, et al., 1994). Positive results have been obtained with potassium nitrate supplementation even with good plant nutritional status, which is possibly related to the lower ability to mobilize mineral reserves necessary for the period (Ruiz et al., 2001). On the other hand, potassium decreases the loss of fruit from splitting (Lavon, et al., 1992); also, GA₃ reduces fruit splitting when applied shortly after the end of the June drop in "Nova" hybrid mandarin (Garcia, et. al. 1994). GA₃ application improved fruit quality (Davies, et al., 1999 and 2001), while KNO3 increased fruit size and juice acidity for Shamuti and Valencia oranges (Erner et. al. 1993).

The purpose of this work is to study the effect of Gibberellic acid (GA_3) and potassium nitrate (KNO3) sprays at different times and concentrations on fruit set, yield, fruit splitting and fruit quality on Washington navel orange trees. Hence, to identify the best treatments for achieve the highest return for the growers.

2. Material and Methods

The experiment was carried out in the private orchard belonged for Mr. Hassan Marie in Benha, El-Kalubiah Governorate, Egypt, in 2008 and 2009 seasons on forty-years-old of "Washington navel" (Citrus Sinensis) orange trees grafted on Sour orange rootstock (Citrus aurantium, L.Obseck) and were planted at 5×5 m spacing in clay soil. Ninety-six "Washington navel" orange trees were divided into twenty four groups according to vigor and number of flowers and used for data collection. The design was a randomized block with 4 single-tree replicates and 8 treatments with 3 time intervals of spray all treatments. The experiment involved the following eight treatments. GA₃ at 50 ppm and 100 ppm plus the same concentrations of GA3 with 0.5% urea: potassium nitrate treatments was used at three levels 2, 4 and 6%; the control trees untreated. Trees were sprayed on full bloom stage (first application), fruit diameter from 1.5-2.0 cm (second application) and both (first and second time of application). The total number of flowers was counted before treatments and commercially available urea containing 46% N and Berlex (containing 92% GA₃ and 8% of other gibberellins) were used in the trials. Triton B at 0.1% was used as a wetting agent for all spraying solutions. In addition foliar spray of potassium treated as KNO₃ 98%. All trees generally received adequate organic and inorganic fertilization. Irrigation was given at intervals of about 10-15 days in summer and 15-21 days in winter. However, a balanced foliar fertilization of all microelements was adopted three times yearly (February, May and August). The following parameters of the studied treatments were carried out.

Percentage of fruit set.

Fruitlets and fruits drop were expressed as an accumulative percentage per tree. Percentage of fruit set = number of fruit set during a given interval \times 100/ number of fruit at the beginning of the interval.

Yield

Weight (kg) and number of mature fruits per tree were recorded at late November of each season.

Fruit splitting percentage

Determination dates of beginning primary symptoms of splitting for each treatment were observed and recorded. Total number of fruits was counted for each tree at the end of July to end of October 2008 and 2009. Percentage of fruit splitting was calculated using the following equation. Fruit splitting percentage = number of splitting fruits × 100/ Total number of fruits.

Nitrite and nitrate contents in fruit juice

A sample of 10 ml of fruit juice was taken from each replicate to determine nitrite and nitrate according to the methods outlined by (Sen and Donaldson, 1978).

Physical properties of fruits

Fruit weight, fruit size, fruit length and diameter and peel thickness for each fruit were measured by using the varinier caliper. Juice volume, also Juice weight percentage was calculated by using the following equation. Juice weight % = average juice weight (gm.) / fruit \times 100 / average fruit weight (gm.).

Chemical properties of fruits

Total soluble solids (T.S.S %) was determined by using Zeiss hand refractometer, total acidity was determined according (A.O.A.C., 1995), also T.S.S/Acid was calculated.

Statistical analysis

The experiment was designed in completely randomized block design with four replicates for each treatment and each replicate was represented by one tree. The obtained data of both seasons were subjected to analysis of variance according to (Clark and Kempson, 1977) and the means were differentiated using Duncan multiple range test at 5% level (Duncan, 1955).

3. Results and Discussion Fruit set percentage

It is obvious from Tables (1&2) that the difference between the use of gibberellic acid and potassium nitrate on fruit set of Washington navel orange were significant. The results revealed that, trees spraying with both GA3 and KNO3 enhanced fruit set, whereas trees treated by GA₃ 50ppm + 0.5% urea gave significantly the highest fruit set percentage at (30, 60,165 and 205 days) after full blooming followed by trees sprayed with GA₃ 50ppm alone, while the lowest values of fruit set percentage were obtained by trees treated by KNO₃ 2% and control treatment meanwhile, the other treatments gave the intermediate values in this regard during the two seasons. On the other hand, concerning the time intervals of spray for all treatments, data revealed that, trees sprayed at (first application+ second application) had the highest significant values for fruit set followed by (first application) while (second application) gave the lowest significant values during two seasons. Several scientific trials show that the gibberellins increase the cell wall flexibility by stimulating the synthesis of new cellulose polymers (Richards et al., 2001). The present results are a

general in harmony with (Davies, 1987) who stated that, gibberellins could reduce the senescence of leaves and fruits. Also; (Brosh, *et al*, 1975 and Tominaga, 1998) reported that, GA₃ and KNO₃ decreased abscission of fruitlets in navel oranges and grapefruit. In addition, potassium nitrate (KNO₃) enhanced fruit set and increased yield of orange and mandarin trees (El-Deeb, 1989; El-Fangary, 1998 and Mostafa, *et al.*, 2005).

Fruit weight (gm)

Results in Table (3) showed that no constant trend during two studied seasons for fruit weight due to different treatments was noticed on Washington navel orange. Whereas, foliar sprays of trees by KNO3 2% scored the highest significant values for fruit weight at the (first and second time of application) in the first season, while trees sprayed with GA3 50ppm gave the maximum values at full bloom stage in the second season. On the other hand, trees treated by GA₃ 100 ppm gave the lowest significant values for fruit weight at (second time of application) and (first and second time of application) in the first season. Meanwhile, the lowest values were on KNO₃ 4% treatment at full bloom stage in the second season. Anyhow, the differences between all treatments were high to be significant.

Fruit number/tree

Data in the Table (3) revealed that, all treatments increased fruit number with some fluctuations as compared with control treatment. On the other hand, it was noticed that the maximum fruit number were obtained during foliar sprays of trees at full bloom stage (first application) and (first and second time of application) while (second application) gave the lowest significant values of fruit number in the first and second season.

Yield

Yield as weight (Kg/tree or ton/fed.) are shown in Table (4) yield was significantly increased by all treatments either with spraying gibberellic acid or with KNO₃ at any concentrations as compare to the control treatment. However, yield was gradually increased by spraying of KNO₃ 2% than the control then the range of increase was higher when trees treated by KNO₃ at 6% then 4 % concentrations and reached the maximum with gibberellic acid (GA₃) treatments especially (GA₃ 50ppm + 0.5%urea) which gave the highest yield (yield Kg/tree and ton/fed.) for the first and second seasons. Also, data revealed that trees sprayed at (first application) and (first and second time of application) scored the higher averages as compared with those sprayed at (second application). From the above results, it is interest to notice that, GA₃ and KNO₃ at different rates spraying increased the yield of Washington navel orange trees. These results are in the same line with those obtained by (Smith, 1993; Babu and Lavania, 1985) in navel orange and (Brosh and Monselise, 1977) in tangerine hybrids; they found that gibberellic acid (GA₃) increased fruit set. Also, (Ibrahim, *et al.* 1994) reported that, trees spraying with GA₃ increased the yield of Washington navel orange. Likewise, (El-Fangary, 1998 and Mostafa, *et al.*, 2005) found that, KNO₃ enhanced fruit set and increased yield of orange and mandarin trees.

Fruit splitting percentage

It is evident from the results shown in Fig. (1&2) that gibberellic acid and potassium nitrate treatments decreased fruit splitting percentage as compared with control treatment especially trees treated by KNO3 6% gave the lowest significant values of fruit splitting due to the peel thickness of fruits which increased with increasing the concentration of potassium nitrate Table (8). This finding is in parallel with the finding of (Josan et al., 1995) in Lemon who reported that the thicker peel helps to resist fruit puncture. While the other treatments gave the intermediate values during two seasons (2008 &2009). Also, it can be noticed that, the splitting tendency is greatly depended on the stage of development of the fruit whereas, full bloom stage (first application)scored the maximum significant average for fruit splitting while, trees treated at (second application) or (first and second time of application) had the minimum significant averages of fruit splitting, although GA3 treatments scored decreasing of fruit peel thickness, these results may be due to the elastic walls of fruit cells as a result of spraying with GA₃ in these stages .This explanation can be agreed with (Richards et al., 2001) they found that, the gibberellins increase the cell wall flexibility by stimulating the synthesis of new cellulose polymers.

Nitrite and nitrate content in fruit juice

As shown in Tables (5& 6) results revealed that, nitrite and nitrate contents in fruit juice were affected by different treatments in the two seasons. It is clear that, trees sprayed with (KNO₃) gave the highest values for nitrite and nitrate in their fruit juice especially with high concentrations, while, trees sprayed with gibberellic acid (GA₃) either 50 ppm alone or plus 0.5 % urea gave the lowest values in fruit juice than the other treatments. This means that, the beneficial effect of spraying GA₃ either 50 ppm or plus 0.5% urea was mainly on reducing nitrite and nitrate in fruit juice. Also, it is noticed from Table (5&6) that the time of applications did not show any

distinctive effect on nitrite and nitrate contents in fruit juice in the first and second seasons. In this respect, (Ibraheem, 1994 and Abd El-Migeed, et al.,

2007) mentioned that, mineral nitrogen fertilization easily forms nitrate in fruit juice as compare with using organic fertilizers.

Physical properties of fruits Fruit diameter and length (mm)

Data in Table (7) indicated that the statistical analysis showed no significant differences between all treatments on Washington navel orange fruits in the first season, while trees sprayed with GA₃ 100 ppm enhanced significant increased fruit diameter and length (mm) in the second season. Anyhow, the differences between all treatments were low to be significant.

Fruit size (mL)

It is clear from Table (8) that, all treatments increased fruit size as comparing with control especially with high concentration of potassium nitrate in the first and second season (2008 &2009 may be due to increasing of fruit peel thickness. The present results are in a general harmony with (Okada, et al., 1994) on Satsuma mandarin they mentioned that fruit size increased as K fertilization increased, also (Abd El-Rahman, 2005) found that spraying with promalin at 45 ppm and GA_3 at 50 ppm increased fruit size on navel orange fruits.

Peel thickness (mm)

Data in Table (8) showed that, peel thickness was affected by different treatments in the first and second seasons, and it is clear that, GA₃ treatments

reduced significant values for fruit peel thickness, on the other hand, it is noticed that, peel thickness increased with increasing the concentration of potassium nitrate. The same observation was reported by (Zaied, *et al.*, 2006) on Washington navel orange.

Juice weight percentage of fruits is shown in Table (9); the changes of juice weight percentage were slightly fluctuated during two seasons. No obvious trend could be detected between all treatments. These results agree with the finding of (Abd El-Rahman, 2005) on navel orange trees, who mentioned that spraying gibberellic acid had no significant effect on juice weight percentage. In the same direction (Davies et al., 1999) stated that, effects of GA₃ on juice fruits were variable, this inconsistency may be related to time of application.

Chemical properties T.S.S percentage:

Table (9) clearly showed that all treatments did not show a constant trend during two seasons for T.S.S percentage in fruit juice of Washington navel orange. Data also indicated that, spraying trees with KNO3 at 4% gave the lowest significant values for T.S.S % comparing with other treatments. Anyhow, the differences between all treatments were low to be

significant.

A similar trend was obtained with navel orange (Ibrahim, *et al.* 1994 and Abel El-Rahman, 2005). On the other hand, (Mostafa and Saleh 2006) found that T.S.S content in the fruit juice increased with potassium sprays on Balady mandarin trees.

Acidity

Table (10) reflects that trees sprayed with GA₃ 50 ppm had the highest significant acidity for Washington navel orange fruits in the first season, while, trees treated by potassium nitrate treatments gave the maximum acidity for their fruits in the second seasons especially with higher concentration. Meanwhile, the other treatments scored the intermediate significant values in this regard for two seasons. These results are in the same line with those obtained by (Ibrahim, et al., 1994) who found that total acidity were no significant effected by GA₃ treatment. Also, (Erner, *et al.* 1993) reported that trees spraying with KNO₃ increased juice acidity on Shamouti and Valencia oranges.

T.S.S acid ratio

It is evident from Table (10) that T.S.S acid ratio did not show any obvious trend in the first and second season. Concerning the time of foliar spraying, the results indicated that trees sprayed at second time (fruit diameter from 1.5-2.0 cm) recorded the highest significant values for T.S.S. acid ratio with KNO₃ 2% followed by GA₃ 100 ppm + 0.5% urea on Washington navel orange fruits than the other times of applications in the first season

(2008). While, GA_3 100 ppm + 0.5% urea gave the highest significant values for T.S.S. acid ratio in (second application and first application) respectively in the second season (2009). Also, it could be noticed that, the differences between all treatments were high to be significant.

Conclusion

From the above mentioned results, it could be concluded that, fruit set, yield as weight ton/fed., and fruit quality especially in respect with reducing nitrite and nitrate in fruit juice of Washington navel orange were greatly improved with spraying trees GA₃ 50 ppm with or without 0.5 % urea. Concerning the application times it could be noticed that, both full bloom (first application) or full bloom + fruit diameter from 1.5-2.0 cm (first and second time of application) gave the best results so, we could be recommended to use (first application) to reduce the costs for growers and giving the best yield and fruit quality. Treatments that increase brix and reduce acid early in the season provide two benefits. Growers can gain the economic advantage of harvesting early and can avoid the economic loss due worsening crease as harvest is delayed as mentioned by (Carol J. Lovatt. 2000).
