Abstract: Advanced oxidation processes (AOPs) have proved very effective in treatment of the various hazardous organic pollutants in water. The photocatalytic degradation of two azo dyes, monoazo dye Acid Orange 10 (AO10) and diazo dye Acid Red114(AR114) present in wastewater were studied. Homogeneous photocatalytic degradation of the two azo dyes with UV/H₂O₂ process was investigated. The rates of disappearance of the two azo dyes were monitored spectrophotometrically at the visible maximum absorption wavelengths. It was found that the rate of decolorization rises by increasing the initial dosage of H₂O₂ up to a “critical” value at which it is maximum and beyond which it is inhibited. The rates of reactions follow pseudo-first-order kinetics. Also heterogeneous photocatalytic degradation of the two azo dyes with UV/TiO₂ (titanium dioxide) interface was investigated. The photocatalytic degradation rate depends on dye structure, dye concentration, TiO₂ concentration and pH of the medium. The mechanism of the photodegradation process under UV-visible light illumination involves an electron excitation into the conduction band of the TiO₂ semiconductor leading to the generation of very active oxygenated species that attack the dye molecules leading to photodegradation. Photocatalytic activity of TiO₂ was examined by focusing on its enhancement by electron scavengers in the photocatalytic decomposition of the two azo dyes. The electron scavengers employed was inorganic oxidant such as H₂O₂, adequate dose of H₂O₂ led to a faster degradation of the two azo dyes in the TiO₂ photocatalytic system. The fast decolorization of monoazo dye (AO10) than diazo dye (AR114) is an indication that, the number of azo and sulphonate groups in the dye molecule may be a determining factor for increasing the degradation rates. [Researcher. 2010;2(9):52-71]. (ISSN: 1553-9865).

Keywords: Azo dyes; UV/H₂O₂ oxidation, Titanium dioxide; Photodegradation; Semiconductor.

1- Introduction

Environmental pollution on a global scale, as well as the lack of sufficient clean energy sources, have drawn much attention to the need for developing ecologically clean chemical technology, materials, and process [1-4]. Azo dyes, being the largest group of synthetic dyes, constitute up to 70% of all the known commercial dyes produced. Highly substituted aromatic rings joined by one or more azo groups characterize their chemical structures. These substituted ring structures make the molecules recalcitrant which the conventional wastewater treatment processes do not degrade. Being released into the environment, these dyes not only impart colors to water sources but also damage living organisms by stopping the reoxygenation capacity of water, blocking sunlight, and therefore disturbing the natural growth activity of aquatic life [5,6]. Thus, the color removal of textile wastewater is a major environmental concern [7].

In recent years, research in new non-biological methods has led to processes which actually destroy these pollutants in stead of simply extracting them from water (e.g., adsorption by active carbon, air stripping, etc.). It has been shown that the use of TiO₂, O₃, H₂O₂, and Fenton (a mixture of ferrous ion with H₂O₂) are more efficient in the photodegradation of organic pollutants in comparison to that of direct photolysis [8-10]. Among them, one of the common observations is that the enhancement of organic decomposition is due to the generation of powerful non-selective hydroxyl radical (•OH) produced in the process of photodegradation.

The efficiency of advanced oxidation processes for the degradation of recalcitrant compounds has been extensively studied [11-16]. Photocatalytic process, which utilizes TiO₂ semiconductor photocatalyst, has received increasing attention because of its low cost, non-toxicity, relatively high chemical stability of the catalyst, and the possibility of using sunlight as a source of irradiation [5,8,11,14]. However, it has a limitation that the quantity of •OH radicals cannot be increased infinitely because overdosing of TiO₂ scatters the light in the solution [8,17]. Therefore, new developments of these technologies have focused on searching for better oxidants to increase the
generation of radicals or to optimize the photodegradation process.

It was reported that the use of inorganic oxidants, such as H$_2$O$_2$, ClO$_3^-$, BrO$_3^-$, and S$_2$O$_8^{2-}$, in TiO$_2$ system increased the quantum efficiencies either by inhibiting electron-hole pair recombination through scavenging conduction band electrons at the surface of TiO$_2$ or by offering additional oxygen atom as an electron acceptor to from the superoxide radical ion (O$_2^-$) [8, 18]. According to the investigation on H$_2$O$_2$, adequate dose of H$_2$O$_2$ led to a faster degradation of organic compounds in the TiO$_2$ photocatalytic system [8, 19]. However, the degradation was suppressed if excess H$_2$O$_2$ was used. This is due to the undesirable consumption of OH radical that was previously formed in the solution by H$_2$O$_2$, leading to generation of less-reactive HO radicals [8, 20]. Enhancement of TiO$_2$-catalyzed photodegradation of organic compounds by several inorganic oxidants was mainly attributed to the increased electron scavenging from the extra oxidant sources [8,21].

Several studies of photocatalytic degradation of dyes have been reported [8,22,23]. Factors influencing the photodegradation rate of aqueous system have been studied in the subjects such as the initial concentration of dyes, the effect of pH values, dissolved oxygen contents and amounts of photocatalyst added to the aqueous solution [24,25].

This paper describes the kinetics of the color removal for two dyes, monoazo dye Acid Orange 10 (AO10) and diazo dye Acid Red 114(AR114) by homogeneous photocatalytic degradation in presence of (UV/H$_2$O$_2$) by Homogeneous which is a ‘friendly’ oxidant and by heterogeneous photocatalytic degradation in presence of (UV/TiO$_2$) and enhancing the photocatalytic activity of TiO$_2$ by employing electron scavenger such as H$_2$O$_2$. Variable factors such as the initial dyes concentration, H$_2$O$_2$ does, TiO$_2$ loading and pH values have been studied.

2. Experimental
2.1. Materials
Two azo dyes, monoazo dye Acid Orange 10 (AO10) and diazo dye Acid Red 114(AR114) were obtained from Lingxian Shine Coating and auxiliaries Co. LTD. were used without further purification. Their structure are depicted below.

![Structure of C.I. Acid Orange 10](image1.png)
(Mol. wt. 452.376 g and $\lambda_{\text{max}}$ 478 nm)

![Structure of C.I. Acid Red 114](image2.png)
(Mol. wt. 830.8308g and $\lambda_{\text{max}}$ 514 nm)

Hydrogen peroxide (30% w/w) was obtained from Merck. Titanium dioxide P-25 from Degussa Corporation (70% anatase, 99.8% purity, average particle size 30 nm and specific surface of 50 m$^2$/g). It was dissolved in deionised water using (New water purification system, Human RO 180. RO, product).

2.2. Physical measurements
For the UV/H$_2$O$_2$ and UV/TiO$_2$ processes, irradiations were performed in a batch photoreactor. All experiments were conducted in a batch microsol light tester equipped with a pre-settable timer and water-cooling jacket (BS 1006 UK-TN) fitted with 400 W MB/U lamp show in Fig. (1) (made in England).
The pH values of the solution were adjusted, using microcomputer pH-vision DATALOGGER 6209; JENCO ELECTRONICS-LTD (made in U.S.A.). PH adjusted using dilute hydrochloric acid and sodium hydroxide solutions. Hydrochloric acid was chosen because its effect on the adsorption surface properties of the TiO$_2$ is negligible [26]. The absorption spectra were recorded with JENWAY-6300 UV-Visible spectrophotometer. The absorbance of solutions measured using a 1cm quartz cell (made in U.K.).

Centrifug model 800 of a maximum speed 4000r/min is used for complete separation for the semiconductor particles used (TiO$_2$) from the sample solution. Scanning electron microscope (SEM) analysis is performed to identify the catalyst surface morphology using a JEOL-JSM-5400S scanning electron microscope (made in Japan). The SEM is measured in National Center for Radiation Research and Technology.

2.3. SEM analysis

The SEM picture of pure TiO$_2$ and (AO10) and (AR114) adsorbed on TiO$_2$ are shown in Fig. (2). The SEM picture of pure TiO$_2$ Fig. 2a shows that the size of titanium dioxide particles are uniform and needle-like particles [9]. In case of (AO10) and (AR114) agglomeration (particle-particle interactions) is observed. The distribution of dye on the surface of TiO$_2$ is not uniform and SEM pictures Fig. 2b,c shows that, dyes contain irregular shaped particles which are the aggregation of tiny crystals. However, it cannot be ruled out, that some dye particles are too small to be observed at the resolution of the used microscope [4,18]. The image from Fig. 2b,c reveals that, the presence of great agglomerates with particle size of monoazo dye (AO10) than diazo dye (AR114). From this result, it is clear that the morphology has been strongly influenced by the type of acid dye [27].

2.4. Photocatalytic degradation experimental

2.4.1. Homogeneous photocatalytic degradation

The experiments are carried out in a batch – type photoreactor. H$_2$O$_2$ is acts as photocatalyst and UV light as illuminating light source. Reaction system is setup by adding the photocatalysts into 250 ml dye solutions prepared in appropriate concentrations using deionized water. The pH is adjusted to the desired values with HCl and NaOH. The dye solutions are stirred and 5 ml samples are withdrawn at regular time intervals and the dye concentrations are measured spectrophotometrically.

2.4.2. Heterogeneous photocatalytic degradation

Also the experiments are carried out in the same batch photoractor. Pure TiO$_2$ powder adding into 250 ml dye solutions prepared in appropriate concentrations using deionized water. The pH also is adjusted to the desired values. The dye solutions are stirred and 5 ml samples are withdrawn at regular time intervals and centrifuged the dye concentrations are measured spectrophotometrically.

3. Results and discussion

3.1. Homogeneous photocatalytic degradation with H$_2$O$_2$

Advanced oxidation processes (AOPs); such as O$_3$, UV/O$_3$ and UV/H$_2$O$_2$ are widely used to decompose organic products in industrial wastewater and groundwater [28]. The extensive literature in this filed has been reviewed [11]. These processes have the potential ability to mineralize most of the organic contaminants into carbon dioxide and water. In AOPs system, the free radicals (OH) are the dominant species contributing to the degradation of organic in wastewater. These processes comprise the activation of hydrogen peroxide, or ozone, with UV light to produce hydroxyl radicals which have a higher oxidation potential (2.8V) than that of hydrogen peroxide (1.78 V).
During the last decade, some investigations have been reported about the successful application of UV/H$_2$O$_2$ process for dye wastewater treatment [8,10,19,29].

It is indisputable that degradation of the dye is due to the hydroxyl radicals generated upon photolysis of hydrogen peroxide [30], following the reaction:

$$H_2O_2 + h \nu \rightarrow 2 \cdot OH$$ \hspace{1cm} (1)

This radical is a very powerful oxidizer, able to react with inorganic [31] as well with aliphatic [32] or aromatic organic compounds [33]. According to the results of Shu et al., [28] the photooxidation reaction is pseudo-first-order with respect to azo dye concentration. This frequently occurs when the contaminant is very dilute in solutions. The kinetic constant can also be linked to the dye concentration by Eq. (2).

$$\ln \frac{C}{C_0} = -Kt$$ \hspace{1cm} (2)

C$_0$ : dye concentration at t =0
C : concentration at time t.

3.1.1. Effect of initial dye concentration

Initial dye concentrations C$_0$ were set in the range 1.0 x 10$^{-5}$ to 1.0 x 10$^{-4}$ M for both two azo dyes Acid Orange 10 and Acid Red 114. Photocatalysis were compared in presence of 5mM H$_2$O$_2$ for both two azo dyes and pH 3.0. Initially, a large degree of removal is observed. This is due to fast decomposition of H$_2$O$_2$ producing the hydroxyl radicals. Moreover, decolorization of dye is mainly due to hydroxyl radicals generated. Azo bonds are more active: AO10 contain one azo bond and AR114 contain two azo bonds and degradation of this dyes are due to the initial electrophilic cleavage of its chromophoric azo (–N=N–) bond attached to naphthalene ring [34].

The values of photodegradation pseudo first order rate constants for different concentrations of dyes calculated from the linear plots of ln A/A$_0$ against irradiation time Fig. (3). Taking into account that, the life-time of hydroxyl radical is very short (only few nanoseconds), they can only react where they are formed [35]. Increasing the concentrations of AO10 and AR114 lead to decrease in the degradation rate see Fig. 4. However, the molar extinction coefficient of two dyes are high ($\varepsilon = 16.9 \times 10^3$ and $18.3 \times 10^3$ liter mole$^{-1}$ cm$^{-1}$) for AO10 and AR114 respectively, so that a rise in its concentration induce an inner filter effect, i.e., incident light would largely be wasted for dye excitation rather than for the hydroxyl radical precursor excitation. Consequently, the solution becomes more and more impermeable to UV radiation. As the rate of hydrogen peroxide photolysis directly depends on the fraction of incident light absorbed by H$_2$O$_2$ molecules, the degradation rate slows down.

3.1.2. Effect of initial H$_2$O$_2$ concentration

The effect of varying the initial H$_2$O$_2$ concentration increase from 5mM to 100 mM for dye concentration 1.0 x10$^{-5}$M at pH 3.0 for both the two azo dyes AO10 and AR114. A very large excess of H$_2$O$_2$ in comparison to the dye was introduced in the solutions. Fig. 5, shows that, the initial hydrogen peroxide concentration strongly modifies the rates of degradation of the two azo dyes, Acid Orange 10 and Acid Red 114 in the UV H$_2$O$_2$ processes [19,29].

An increase of the hydrogen peroxide concentration up to 50 mM leads to an important rise in the solution discoloration rate. On the other hand, further increase in the H$_2$O$_2$ concentration partly inhibits the oxidation rate. This behaviour is proof of the existence of an optimal dosage in H$_2$O$_2$.

We must underline the fact that hydroxyl radicals produced upon photolysis of hydrogen peroxide can react with dye molecules, but also with an excess of H$_2$O$_2$.

$$\cdot OH + H_2O_2 \rightarrow HO_2^- + H_2O_2$$ \hspace{1cm} (3)

At low hydrogen peroxide concentrations, formation of $\cdot OH$ is the kinetic determining step. H$_2$O$_2$ cannot generate enough hydroxyl radicals and the oxidation rate is logically slow. Further, most of free radicals are directly consumed by the dye. In the presence of high concentration of peroxide, we could expect that more $\cdot OH$ radicals...
would be produced. However these radicals preferentially react with the excess of $\text{H}_2\text{O}_2$. This undesirable reaction competes with the destruction of the dye chromophore [36,37].

### 3.1.3. Effect of initial pH

To study the effect of pH on photodegradation, experiments are conducted at $1.0 \times 10^{-5}$M dye concentration for the two azo dyes Acid Orange 10 and Acid Red 114 in presence of 50mM $\text{H}_2\text{O}_2$ dose at different initial pH values ranges from 1.0 to 11.0, the calculated pseudo first-order rate constants show from Fig. (6). The results show that, high degradation rate constant values are observed at pH 3.0 for both two azo dyes and decrease significantly in alkaline media. Similar results have already been reported for azo dyes [35,36].

The high rate constant value observed at lower pH can be explained by the change in the molecule structure. The presence of labile H atom makes the molecule of dye especially vulnerable toward attack of $^\cdot\text{OH}$ radicals [36].

In alkaline medium, hydrogen peroxide undergoes decomposition leading to dioxgen and water rather than producing hydroxyl radicals under UV irradiation [38]. Therefore the instantaneous concentration in $^\cdot\text{OH}$ is lower than expected. The base – catalyzed decomposition involves the $\text{HO}_2^-$ anion: the conjugated base of $\text{H}_2\text{O}_2$ reacts with non-dissociated molecule of $\text{H}_2\text{O}_2$ according to Eq. (4).

$$\text{HO}_2^- + \text{H}_2\text{O}_2 \rightarrow \text{H}_2\text{O} + \text{O}_2 + ^\cdot\text{OH} \quad (4)$$

Furthermore, the deactivation of $^\cdot\text{OH}$ is greater when the pH of the solution is high (the reaction of $^\cdot\text{OH}$ with $\text{HO}_2^-$ being approximately 100 times faster than its reaction with $\text{H}_2\text{O}_2$ [30,38].

$$^\cdot\text{OH} + \text{HO}_2^- \rightarrow \text{H}_2\text{O} + \text{O}_2^- \quad (5)$$

$$\text{H}_2\text{O}_2 + ^\cdot\text{OH} \rightarrow \text{H}_2\text{O} + \text{HO}_2^- \quad (6)$$

The reactivity of $\text{HO}_2^-$ and its basic form $\text{O}_2^-$ with organic compounds is very weak. They preferentially disproportionate producing some hydrogen peroxide and oxygen, according to the Eq. (7).

$$\text{HO}_2^- + \text{O}_2^- + \text{H}_2\text{O} \rightarrow \text{H}_2\text{O}_2 + \text{O}_2 + ^\cdot\text{OH} \quad (7)$$

### 3.2. Heterogeneous photocatalytic degradation

A wide variety of organics are introduced into the environment through various sources such as industrial effluents, agricultural runoff and chemical spills. Industrial effluents contain several non-biodegradable substrates that can be harmful to the environment [3,4]. One major source of these effluents is the waste arising from the industrial process, which utilizes dyes to color paper, plastic and natural and artificial fibers [39]. A substantial amount of dyestuff is lost during the dyeing process in the textile industry, which poses a major problem for the industry as well as a threat to the environment [39], and decolorization of dye effluents has therefore acquired increasing attention. During the past two decades, photocatalytic process involving $\text{TiO}_2$ semiconductor particles under UV light illumination has been shown to be potentially advantageous and useful in the treatment of wastewater pollutants.

#### 3.2.1. Photocatalysis of $\text{TiO}_2$ suspension containing azo dyes

##### 3.2.1.1 Photodegradability of the dyes

Initial control experiments are carried out in order to evaluate the photocatalysis viability in the degradation of the azo dyes AO10 and AR114 under the following conditions: (i) self photolysis of dye solution with UV light; (ii) dye solution with catalyst in dark and (iii) under irradiation of UV light with photocatalyst Fig. (7) shows the change in absorption intensity on irradiation of an aqueous solutions of AO10 and AR114, in the presence and absence of titanium dioxide.

From the above results it is clear that the dyes are remarkable decolorization to (i) direct photolysis of UV light and (ii) in the presence of $\text{TiO}_2$ alone. Simultaneous irradiation and aeration in the presence of $\text{TiO}_2$ caused
excellent decolourisation of the dyes [40]. This suggested that the photocatalytic activity of TiO$_2$ degussa P-25 is remarkable, and the photocatalytic degradation of these dyes under UV light are possible[41-43]. This is due to the fact that when TiO$_2$ is illuminated with the light of $\lambda<390$nm conduction band electrons (e$^-$) and valence band holes (h$^+$) are generated. TiO$_2$ suspension is irradiated with light energy greater than its band gap energy (E$_g$, 3.2 eV). The photogenerated electrons could reduce the dyes or react with electron acceptors such as O$_2$ adsorbed on the Ti(III) surface or dissolved in water, reducing it to superoxide radical anion O$_2^{-}$. The photogenerated holes can oxidize the organic molecule to form R$,^+$, or react with OH$^-$ or H$_2$O oxidizing them into $\dot{\text{OH}}$ radicals. Together with other highly oxidant species (peroxyl radicals) they are reported to be responsible for the heterogeneous TiO$_2$ photodecomposition of organic substrates as dyes. According to this, the relevant reactions at the semiconductor surface causing the degradation of dyes can be expressed as follows:

$$\text{TiO}_2 + h(v_{\text{UV}}) \rightarrow \text{TiO}_2 (e_{\text{CB}}^- + h_{\text{VB}}^+) \quad (8)$$

$$\text{TiO}_2 (h_{\text{VB}}^+) + \text{H}_2\text{O} \rightarrow \text{TiO}_2 + \text{H}^+ + \dot{\text{OH}} \quad (9)$$

$$\text{TiO}_2 (h_{\text{VB}}^+) + \text{OH} \rightarrow \text{TiO}_2 + \dot{\text{OH}} \quad (10)$$

$$\text{TiO}_2 (e_{\text{CB}}^-) + \text{O}_2 \rightarrow \text{TiO}_2 + \text{O}_2^- \quad (11)$$

$$\text{O}_2^- + \text{H}^+ \rightarrow \text{HO}_2^- \quad (12)$$

$$\text{Dye} + \dot{\text{OH}} \rightarrow \text{degradation products} \quad (13)$$

$$\text{Dye} + h_{\text{VB}}^+ \rightarrow \text{oxidation products} \quad (14)$$

$$\text{Dye} + e_{\text{CB}}^- \rightarrow \text{reduction products} \quad (15)$$

The resulting $\dot{\text{OH}}$ radicals, being a very strong oxidizing agent can oxidize most of azo dyes to the mineral end-products. Substrates not reactive toward hydroxyl radicals are degraded employing TiO$_2$ photocatalysis with rates of decay highly influenced by the semiconductor valence band edge position [44]. The role of reduced pathway (Eq. (15)) in heterogeneous photocatalysis has been investigated also in the degradation of several dyes but in a minor extent than oxidation [43,45].

### 3.2.1.2. Factors influencing the photocatalytic degradation

#### 3.2.1.2.1 Effect of initial dye concentration

The effect of initial concentration of the dye on the rate of degradation was performed by varying the initial dye concentration from $1.0 \times 10^{-3}$ to $1.0 \times 10^{-4}$M (pH = 3.0) with constant loading (0.2 g/l TiO$_2$) for both two azo dyes AO10 and AR 114.

The values of the calculated first order rate constants Fig. (8) were calculated. It is generally noted that the degradation rate increases with the increase in dyes concentrations to a certain level [1.0 $\times 10^{-5}$M] for both two azo dyes and a further increase in dyes concentrations lead to decrease the degradation rate of the dyes [46,47]. The rate of degradation relates to the probability of $\dot{\text{OH}}$ radicals formation on the catalyst surface and to the probability of $\dot{\text{OH}}$ radicals and reacting with dye molecules. As the initial concentrations of the dye increase the probability of reaction between dye molecules and oxidizing species also increases, leading to an enhancement in the decolorization rate. On the contrary, the degradation efficiency of the dye decreases as the dye concentration increases further. The presumed reason is that at high dye concentrations the generation of $\dot{\text{OH}}$ radicals on the surface of catalyst is reduced since the active sites are covered by dye ions. Another possible cause for such results is the UV-screening effect of the dye itself. At a high dye concentration, a significant amount of UV may be absorbed by the dye molecules rather than the TiO$_2$ particles and that reduce the efficiency of the catalytic reaction because the concentrations of $\dot{\text{OH}}$ and O$_2^{-}$ decrease [40,48].

The major portion of degradation occurs in the region near to the irradiated side (termed as reaction zone) where the irradiation intensity is much higher than in the other side [49]. Thus at higher dye concentration, degradation decreases at sufficiently long distances from the light source or the reaction zone due to the retardation in the penetration of light.
Hence, it is concluded that as initial concentration of the dye increases, the requirement of catalyst surface needed for the degradation also increases [50].

3.2.1.2. Effect of TiO₂ loading

TiO₂ dosage is an important parameter that can affect the degradation rate. The initial reaction rates were found to be directly proportional to catalyst concentration indicating the heterogeneous regime. However, it was observed that above a certain level of concentration the reaction rate decreases and becomes independent of the catalyst concentration.

In this work, the effect of TiO₂ loading on the photodegradation rate of the two azo dyes AO10 and AR114 have been examined by varying its amount from 0.05 to 0.2 g/l ([AO10]=[AR114]= 1.0x 10⁻⁵M, pH = 3.0 for both two azo dyes). The calculated linear plots of ln A/A₀ against irradiation time Fig. (9) and photodegradation rate constants for both two azo dyes are given in Fig. (10). Fig. (10) shows that, the rate of photodegradation increase with catalyst loading up to 0.2 g/l. Above this loading, increase in turbidity of the solution reduces the light transmission through the solution. While below this level, it is assumed that the catalyst surface and absorption of light by the catalyst are the limiting factors. Many authors have investigated the reaction rate as a function of catalyst loading under different experimental conditions [51]. The enhancement of the removal rate is due to (i) the increase in the amount of catalyst weight which increases the number of dye molecules adsorbed (ii) the increase in the density of particles in the area of illumination [34]. Thus higher amount of the catalyst may not be useful both in view of possible aggregation as well as reduced irradiation field due to increase in light scattering [52] Wei and Wan have reported that, the catalyst amount has both positive and negative impact on the photodecomposition rate. Furthermore, rate may decrease as a result of loss in surface area available for light-harvesting occasioned by agglomeration (particle-particle interactions) at high solid concentration.

3.2.1.2.3. Effect of pH

The interpretation of pH effects on the efficiency of dye photodegradation process is a very difficult task because of its multiple roles. First, is related to the ionization state of the surface according to the following reactions,

\[
\text{TiOH} + \text{H}^+ \leftrightarrow \text{TiOH}_2^+ \\
\text{TiOH} + \text{OH}^- \leftrightarrow \text{TiO}^- + \text{H}_2\text{O}
\]

as well as to that of reactant dyes and products such as acids and amines. pH changes can be thus influence the adsorption of dye molecules onto the TiO₂ surfaces, an important step for the photocatalytic oxidation to take place [53]. Bahnemann et al. [54] have already reviewed that acid-base properties of the metal oxide surfaces can have considerable implications upon their photocatalytic activity. The point of zero charge (PZC) of the TiO₂ (Degussa P-25) is at pH 6.8 [55]. Thus, the TiO₂ surface is positively charged in acidic media (pH<6.8), whereas it is negatively charged under alkaline conditions (pH>6.8).

Second, hydroxyl radicals can be formed by the reaction between hydroxide ions and positive holes. The positive holes are considered as the major oxidation species at low pH whereas hydroxyl radicals are considered as the predominant species at neutral or high pH levels [48]. It was stated that in alkaline solution \( \cdot \text{OH} \) are easier to be generated by oxidizing more hydroxyle ions available on TiO₂ surface, thus the efficiency of the process is logically enhanced [42]. Similar results are reported in the photocatalysed degradation of acidic azo dyes and triazine containing azo dyes [50], although it should be noted that in alkaline solution there is a coulombic repulsion between the negative charged surface of photocatalyst and the hydroxide anions. This fact could prevent the formation of \( \cdot \text{OH} \) and thus decrease the photoxidation. Very high pHs have been found favorable even when anionic azo dyes should hamper adsorption on the negatively charges surface [56]. At low pH, reduction by electrons in conduction band may play a very important role in the degradation of dyes due to the reductive cleavage of azo bonds.

Third the TiO₂ particles tend to agglomerate under acidic condition and the surface area available for dye adsorption and photon absorption would be reduced [53]. Hence, pH plays an important role both in the characteristics of textile waters and in the reaction mechanisms that can contribute to dye degradation, namely, hydroxyl radical attack, direct oxidation by the positive hole and direct reduction by the electron in the conducting band.

The wastewater from textile industries usually has a wide range of pH values. Generally, pH plays an important role both in the characteristics of textile wastes and generation of hydroxyl radicals [50]. Hence, attempts
have been made to study the influence of pH in the degradation of the two azo dyes AO10 and AR114. The photocatalytic reactions are conducted at different pH values its range from 1.0 to 11.0 and two dyes concentration [1.0 x 10^{-5}M] at catalyst loading of 0.2 g/l. All reactions followed an apparent first-order kinetics confirmed by the linear transform of ln (A/A_0) = f(t). The rate constants of disappearance k in min^{-1} for two azo dyes AO10 and AR114 are illustrated in Fig. (11).

The results obtained in Fig. (11) indicated that, at pH<6 a strong adsorption of the two azo dyes on the TiO_2 particles is observed as a result of the electrostatic attraction of the positively charged TiO_2 with the dyes. At pH>6.8 the two azo dyes molecules are negatively charged in alkaline media, their adsorption is also expected to be affected by an increase in the density of TiO^- groups on the semiconductor surface. Thus, due to coulombic repulsion the dyes are scarcely adsorbed [42]. For the above reasons the photocatalytic activity of anionic dyes (mainly sulphonated dyes) reached a maximum in acidic conditions followed by a decrease in the pH range 7-11 [40,43,47].

Moreover, the higher degradation rate at acid pH is seen also for vis/TiO_2 experiments due to the efficient electron-transfer process due to strong surface complex bond formation. This effect is less marked in neutral/basic pH solutions [57]. The inhibitory effect seems to be more pronounced in the alkaline range (pH=11-13). At high pH values the hydroxyl radicals are rapidly scavenged and they do not have the opportunity to react with dyes [58].

Since the influence of the pH is dependent on dye type and on properties of TiO_2 surface his effect on the photocatalytic efficiency must be accurately checked before any application.

### 3.2.2. Photocatalysis of TiO_2 suspension with H_2O_2 containing azo dyes

It was observed that H_2O_2 addition was beneficial for the photoxidation of the two azo dyes AO10 and AR114 [46]. The reactive radical intermediate $\cdot$OH formed from H_2O_2 by reactions with the photogenerated electrons can exert a dual function: as strong oxidant themselves and as electron scavengers, thus inhibiting the electron-hole recombination the semiconductor surface [59] according to the following equations:

\[
\text{H}_2\text{O}_2 + \text{O}_2^- \rightarrow \cdot\text{OH} + \text{OH}^- + \text{O}_2 \quad (19)
\]

\[
\text{H}_2\text{O}_2 + hv \rightarrow 2 \cdot\text{OH} \quad (1)
\]

\[
\text{H}_2\text{O}_2 + e_{CB}^- \rightarrow \cdot\text{OH} + \text{OH}^- \quad (20)
\]

Moreover, the solution phase may at times be oxygen starved, because of either oxygen consumption or slow oxygen mass transfer. Peroxide addition thereby increases the rate towards what it would have been an adequate oxygen supply. However, H_2O_2 can also become a scavenger of valence band holes and $\cdot$OH, when present at high concentration, [40].

\[
\text{H}_2\text{O}_2 + 2 \text{hVB}^+ \rightarrow \text{O}_2 + 2\text{H}^+ \quad (21)
\]

\[
\text{H}_2\text{O}_2 + \cdot\text{OH} \rightarrow \text{H}_2\text{O} + \text{HO}_2^- \quad (6)
\]

\[
\text{HO}_2^- + \cdot\text{OH} \rightarrow \text{H}_2\text{O} + \text{O}_2 \quad (22)
\]

As both $\text{hVB}^+$ and $\cdot\text{OH}$ are strong oxidants for dyes, the photocatalytic oxidation will be inhibited when H_2O_2 level gets too high. Furthermore, can be adsorbed onto TiO_2 particles to modify their surfaces and subsequently decrease its catalytic activity.

In this work, the effect of varying dose of H_2O_2 [5mM-100mM] in presence of constant weight of TiO_2 (0.05 g/l) were also studied in the presence of the two azo dyes [AO10 and AR114] = 1.0 x 10^{-5}M at constant pH=3.0 Fig. (12). The results demonstrate that the rate of photodegradation enhances from 50mM H_2O_2 without TiO_2 to 10mM H_2O_2 in presence of 0.05 g/l TiO_2 for AO10, while the rate of photodegradation was fixed at 50 mM H_2O_2 for AR 114 without TiO_2 and in presence of 0.05 g/l TiO_2 Fig. (13). On the other hand, the effect of TiO_2 loading on the photodegradation rates of AO10 and AR114 has been examined by varying its amount from 0.05 to 0.20 g/l, ([AO10] = [AR114]= 1.0 x 10^{-5}M), pH=3.0, [H_2O_2]=10mM-50mM for AO10 and AR114 respectively. The calculated photodegradation rate constants are given in Fig. (14), the results, demonstrate that the rate of photodegradation increase with catalyst loading up to [0.05 g/l TiO_2] and in...
presence of 10 mM H₂O₂ for AO10 while the catalyst loading was [0.20 g/l TiO₂] without H₂O₂ for the same dye Fig. (10). Also the rate of photodegradation of AR114 increases to 0.20 g/l TiO₂ without H₂O₂ Fig. (10), while in presence of 50 mM H₂O₂ the catalyst loading was enhances to 0.15 g/l TiO₂ Fig. (14).

Also the concentrations of the two azo dyes were enhanced to (5.0 x 10⁻⁵M) for (AO10) and (1.0 x 10⁻⁴M) for (AR114) in presence of 0.05 g/l TiO₂ with 10 mM H₂O₂ for (AO10) and 0.15 g/l TiO₂ with 50mM H₂O₂ for (AR114) at pH 3.0. The photodegradation rates reached to maximum at 75.4x10⁻³ (min⁻¹) for (AO10) and 42.9x10⁻³ (min⁻¹) for (AR114) Fig. (15). The effect of use TiO₂ with H₂O₂ on the pH values was fixed at pH 3.0 for both two azo dyes [1.0 x 10⁻⁵M].

From the above results it were found that, there were optimum conditions for each process to obtain excellent degradation for each dye. Effect of use UV/H₂O₂ and UV/TiO₂ on (AO10) and (AR114) was 50 mM H₂O₂ and 0.20 g/l TiO₂ for both two azo dyes. The effect enhances in presence of UV/H₂O₂/TiO₂ and becomes 10mM H₂O₂ and 0.05 g/l TiO₂ for (AO10) and 50 mM H₂O₂ and 0.15 g/l TiO₂ for (AR114) Fig. (16).

3.2.3 Efficiency of the recyled catalyst
Photocatalysis is a clean technology, which normally dose not involve any waste disposal problem. The catalysts can be recycled. TiO₂ can be used at least twice without significant change in the efficiency [60]. The economy of the photocatalytic process depends upon how many times a catalyst can be reused without sacrificing its efficiency and the type of regeneration it requires.

The photodegradation rates of the two recycled catalysts RC-1 and RC-1 and RC-2 were examined. RC-1 achieves 50.4 x 10⁻³ (min⁻¹) for (AO10) and RC-2 achieved 43.8 x 10⁻³ (min⁻¹) for (AR114) compared to 73.2 x 10⁻³ and 42.9 x 10⁻³ (min⁻¹) for (AO10) and (AR114) respectively obtained with the fresh catalyst under the same experimental conditions. The used catalyst was regenerated to get RC-1 first by treating with boiling distilled water till a colorless wash liquid was obtained and then by drying it in a hot air oven at a temperature of 90 to 100°C. RC-1 was heated in a muffle furnate at about 600°C to yield RC-2.

The decrease in the efficiency of the recycled catalyst may be attributed to the deposition of photoinsensitive hydroxides (Fouling) on the photocatalysts surface blocking its active sites.

4. Conclusion

The impact of H$_2$O$_2$ initial concentration in color removal kinetics under UV/H$_2$O$_2$ process for two azo dyes monoazo dye (AO10) and diazo dye (AR114) was investigated. The results prove that the pseudo-first order kinetic model is in good agreement with the experimental data. A set of parameters for the model depicting this degradation were determined. These parameters, will naturally vary with the operating conditions, such as (dye concentration, H$_2$O$_2$ dose, pH values). An increase in H$_2$O$_2$ dose leads to a faster degradation up to a critical value; at a higher ratio the degradation process become slower.

The photodegradation of two azo dyes catalyzed by UV/TiO$_2$ was carried out in good results. Various parameters such as (dye concentration, TiO$_2$ leading, pH values) were tested. The photocatalytic degradation rate was enhanced in presence of UV/H$_2$O$_2$/TiO$_2$.

In summary, this work demonstrates that photocatalysis is a very effective technology for degrading Acid dyes with azo and sulphonic groups. Moreover, this technology can be utilized directly in dye baths before they are mixed with other textile effluents, which make their treatment difficult and costly due to dilution.
